

p. 189: 41-42, 59-61, 63, 65-66

41. If  $f(x) = 2x^3 - 3x^2$  then using the limit definition we find

$$\begin{aligned} f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{2(x+h)^3 - 3(x+h)^2 - (2x^3 - 3x^2)}{h} \\ &= \lim_{h \rightarrow 0} \frac{2x^3 + 6x^2h + 6xh^2 + 2h^3 - 3x^2 - 6xh - 3h^2 - 2x^3 + 3x^2}{h} \\ &= \lim_{h \rightarrow 0} \frac{6x^2h + 6xh^2 + 2h^3 - 6xh - 3h^2}{h} = \lim_{h \rightarrow 0} \frac{h(6x^2 + 6xh + 2h^2 - 6x - 3h)}{h} \\ &= \lim_{h \rightarrow 0} (4x^2 + 4xh + 2h^2 - 6x - 3h) = 6x^2 - 6x. \end{aligned}$$

Then using the limit definition again,

$$\begin{aligned} f''(x) &= \lim_{h \rightarrow 0} \frac{f'(x+h) - f'(x)}{h} = \lim_{h \rightarrow 0} \frac{6(x+h)^2 - 6(x+h) - (6x^2 - 6x)}{h} \\ &= \lim_{h \rightarrow 0} \frac{6x^2 + 12xh + 6h^2 - 6x - 6h - 6x^2 + 6x}{h} = \lim_{h \rightarrow 0} \frac{12xh + 6h^2 - 6h}{h} = \lim_{h \rightarrow 0} \frac{h(12x + 6h - 6)}{h} \\ &= \lim_{h \rightarrow 0} (12x + 6h - 6) = 12x - 6 \text{ which is (D)}. \end{aligned}$$

42. If  $f(x) = x^3$ , then  $f'(x) = 3x^2$ , and  $f''(x) = 6x$ , and  $f'''(x) = 6$ , which is a constant function so  $f^{(iv)}(x) = 0$  which is option (D).

59. Call the curve with the positive  $y$ -intercept  $g$  and the other curve  $h$ . Notice that  $g$  has a maximum (horizontal tangent) at  $x = 0$ , but  $h \neq 0$ , so  $h$  cannot be the derivative of  $g$ . Also notice that where  $g$  is positive,  $h$  is increasing. Thus  $h = f$  and  $g = f'$ . Now  $f'(-1)$  is negative since  $f'$  is below the  $x$ -axis there and  $f''(1)$  is positive since  $f$  is concave upward at  $x = 1$ . Therefore,  $f''(1)$  is greater than  $f'(-1)$ .

60. Call the curve with the smallest positive  $x$ -intercept  $g$  and the other curve  $h$ . Notice that where  $g$  is positive in the first quadrant,  $h$  is increasing. Thus  $h = f$  and  $g = f'$ . Now  $f'(-1)$  is positive since  $f'$  is above the  $x$ -axis there and  $f''(1)$  appears to be zero since  $f$  has an inflection point at  $x = 1$ . Therefore,  $f'(1)$  is greater than  $f''(-1)$ .

61.  $a = f, b = f', c = f''$ . We can see this because where  $a$  has a horizontal tangent,  $b = 0$ , and where  $b$  has a horizontal tangent,  $c = 0$ . We can immediately see that  $c$  can be neither  $f$  nor  $f'$  since at the points where  $c$  has a horizontal tangent, neither  $a$  nor  $b$  is equal to 0.

63. We can see immediately that  $a$  is the graph of the acceleration function, since at the points where  $a$  has a horizontal tangent, neither  $c$  nor  $b$  is equal to 0. Next, we note that  $a = 0$  at the point where  $b$  has a horizontal tangent, so  $b$  must be the graph of the velocity function, and hence  $b' = a$ . We conclude that  $c$  is the graph of the position function.

$$\begin{aligned}
 65. f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{3(x+h)^2 + 2(x+h) + 1 - (3x^2 + 2x + 1)}{h} \\
 &= \lim_{h \rightarrow 0} \frac{3x^2 + 6xh + 3h^2 + 2x + 2h + 1 - 3x^2 - 2x - 1}{h} = \lim_{h \rightarrow 0} \frac{6xh + 3h^2 + 2h}{h} \\
 &= \lim_{h \rightarrow 0} \frac{h(6x + 3h + 2)}{h} = \lim_{h \rightarrow 0} (6x + 3h + 2) = 6x + 2
 \end{aligned}$$

$$\begin{aligned}
 f''(x) &= \lim_{h \rightarrow 0} \frac{f'(x+h) - f'(x)}{h} = \lim_{h \rightarrow 0} \frac{6(x+h) + 2 - (6x + 2)}{h} \\
 &= \lim_{h \rightarrow 0} \frac{6x + 6h + 2 - 6x - 2}{h} = \lim_{h \rightarrow 0} \frac{6h}{h} = \lim_{h \rightarrow 0} 6 = 6
 \end{aligned}$$

We see from the graph that our answers are reasonable because the graph of  $f'$  is that of a linear function and the graph of  $f''$  is that of a constant function.

$$\begin{aligned}
 66. f'(x) &= \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \frac{(x+h)^3 - 3(x+h) - (x^3 - 3x)}{h} \\
 &= \lim_{h \rightarrow 0} \frac{x^3 + 3x^2h + 3xh^2 + h^3 - 3x - 3h - x^3 + 3x}{h} = \lim_{h \rightarrow 0} \frac{3x^2h + 3xh^2 + h^3 - 3h}{h} \\
 &= \lim_{h \rightarrow 0} \frac{h(3x^2 + 3xh + h^2 - 3)}{h} = \lim_{h \rightarrow 0} (3x^2 + 3xh + h^2 - 3) = 3x^2 - 3
 \end{aligned}$$

$$\begin{aligned}
 f''(x) &= \lim_{h \rightarrow 0} \frac{f'(x+h) - f'(x)}{h} = \lim_{h \rightarrow 0} \frac{3(x+h)^2 - 3 - (3x^2 - 3)}{h} = \lim_{h \rightarrow 0} \frac{3x^2 + 6xh + 3h^2 - 3 - 3x^2 + 3}{h} \\
 &= \lim_{h \rightarrow 0} \frac{6xh + 3h^2}{h} = \lim_{h \rightarrow 0} \frac{h(6x + 3h)}{h} = \lim_{h \rightarrow 0} (6x + 3h) = 6x
 \end{aligned}$$

We see from the graph that our answers are reasonable because the graph of  $f'$  is that of an even function ( $f$  is an odd function) and the graph of  $f''$  is that of an odd function. Furthermore,  $f' = 0$  when  $f$  has a horizontal tangent and  $f'' = 0$  when  $f'$  has a horizontal tangent.
